

## Module 02 Lab Reflection

Steven Ford

I've found that coding is like a language that can use a framework for communicating what you want to happen. As a sentence has a subject and verb, there are set commands and inputs that will produce something like in this lab we made data visualizations. Despite my lack of experience coding, I'm able to connect to this pattern in coding and as I find more tools for programming, I'm finding it easier to process data.

In class, we talked about thinking about machine learning programs in a supervised learning environment and how it needs intentional processing of data features. This lab gave examples of how we can input data with tools like Pandas, NumPy and Matplotlib to process the data and create visualizations. While this exposed us to the processing of data, it also gave examples of what kind of data would process well for this program. In this lab we looked at three categories of data; samples, features and classes. I know when we process data for machine learning, there's a level of categorization that we as programmers must do to help give guardrails to the machine in understanding inputs.

I'm interested in processing vocal data and curious to the differences and similarities between flora features and haptic data. This may be tangential to the lab, but I've been thinking on the midterm project and would like to create a program that can recognize and categorize sound features of videos similar to shazam but for viral internet clips. I'd collect sample videos and write out sound features like tone, pitch, volume, and classify them as something. I'm not sure yet on the limitation of coding when it comes to classification of sound, but I'd find it really

cool if there was a program that could listen to a video and tell whether it was viral, and what it might be viral for whether it would be something funny, impressive or tragic.
